Project Details

ROSES ID: NNH05ZDA001N
Selection Year: 2006
Program Element: Independent Investigation

Topic: Shock acceleration of solar energetic particles by interplanetary CMEs

Project Title:
Solar wind geoeffectiveness as a function of IMF and dynamic pressure and its effect on high-latitude ionospheric energy deposition

PI Name: Athanasios Boudouridis
PI Email: thanasis@atmos.ucla.edu
Affiliation: University of California, Los Angeles

Project Member(s):
- Anderson, Phillip Charles; Collaborator; University of Texas at Dallas
- Lyons, Larry; Co-I; UCLA;
- Zesta, Efythia; Co-I; NASA Goddard Space Flight Center
- Ridley, Aaron James; Collaborator; University of Michigan

Summary:
The electric field and particle precipitation patterns at high latitudes are two of the most significant considerations for determining the ionospheric state during steady or variable solar wind and Interplanetary Magnetic Field (IMF) conditions. It is therefore of primary importance to fully understand what drives the electric fields and particle precipitation at high latitudes.

It is well known that the IMF is the major contributor to geomagnetic activity on Earth. Recent studies, however, have shown that solar wind dynamic pressure variations cause global effects when they encounter the terrestrial magnetosphere, strongly affecting the magnetosphere, ionosphere, and upper atmosphere. In particular, it has been shown that solar wind dynamic pressure enhancements significantly increase particle precipitation and cause global intensification of the aurora, thus significantly increasing the deposition of energy in the Earth's upper atmosphere. In addition, the extent of the enhanced energy deposition is dependent on the preexisting state of the magnetosphere, which is controlled by the IMF orientation.

Further studies have demonstrated that solar wind pressure increases also affect the cross-polar-cap potential drop (CPCP), and thus the coupling efficiency between the solar wind and the
Earth's magnetosphere in ways that cannot be accounted for solely by the existing solar wind electric field. It is rather the combined contribution of IMF and dynamic pressure, in ways that are yet to be determined, that controls the coupling efficiency between the solar wind and the magnetosphere. Therefore, the pressure enhancements and IMF variations affect both the solar wind geoeffectiveness and the energy input in the high-latitude ionosphere and upper atmosphere. We propose to study the relative contribution of solar wind dynamic pressure, IMF Bz, and IMF By to solar wind geoeffectiveness during steady and variable conditions, and investigate under which circumstances the correlation between solar wind geoeffectiveness and high-latitude energy deposition is the highest. For this purpose we will utilize a combination of solar wind measurements, low-altitude Defense Meteorological Satellite Program (DMSP) data, and results of the Assimilative Mapping of Ionospheric Electrodynamics (AMIE) technique.

We will focus our research on the following scientific questions:

1) What is the effect of different IMF orientations and solar wind dynamic pressure levels on the solar wind-magnetosphere coupling efficiency under steady conditions? 2) How do variations of dynamic pressure and IMF modify the CPCP and the coupling efficiency? 3) How permanent or transient are these responses for step-like changes in the solar wind, and what are the relevant timescales? 4) What is the relative contribution of dynamic pressure and IMF orientation to the CPCP and solar wind geoeffectiveness under steady or changing conditions? 5) How do IMF orientation, dynamic pressure levels, and their changes affect high-latitude energy deposition as measured by the intensity of precipitating flux or ionospheric Joule heating?
